

# CPE102 Programming II

Week 5

*Pointers*

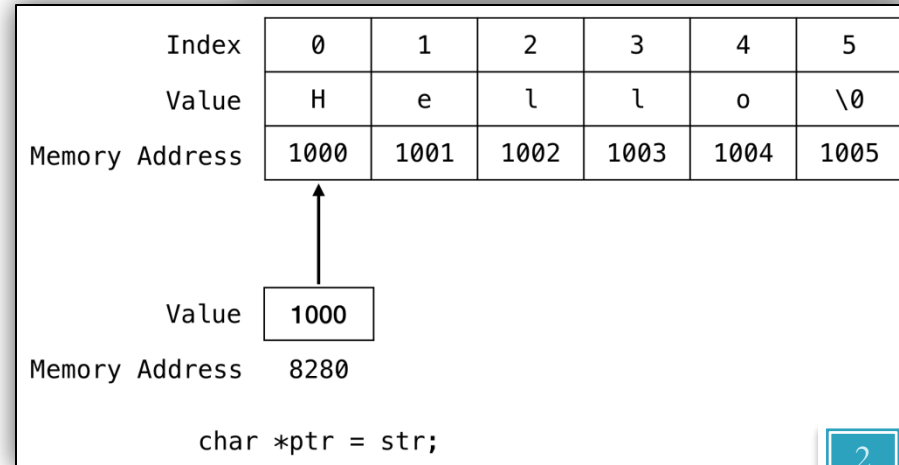

Dr. Nehad Ramaha,  
Computer Engineering Department  
Karabük Universities

# Relationship Between Pointers and Arrays

- ▶ An **array name can be thought as a constant pointer**. The array name **str** **points at the first location** of the allocated memory locations of the array.
- ▶ Arrays and Pointers are closely related.
- ▶ **Pointers can also point arrays** like they point variables.  
`char str[6] = "Hello";`  
`char *ptr;`  
`ptr = str; // Now ptr[0] and str[0] is same.`
- ▶ To explicitly assign ptr to the address of first element of str use **`ptr = &str[0]`**

Variable	Index	Value	Address
str	0	H	1000
	1	e	1001
	2	l	1002
	3	l	1003
	4	o	1004
	5	\0	1005

# Incrementing pointer variable

- ▶ We can use the pointers to access the elements of the array:

`*(ptr+ n) ; // n indicates the index number of the array element`

`*(ptr+ 4); // gets the value of element str[4]`

- ▶ Other alternatives for `str[4]`

`ptr[4]`

`*(str + 4)`

- ▶ we can increment the pointer variable to points to the next memory location based on the size of the data type.

`ptr++`

`Ptr--`

# Pointers and Arrays, Example

```
ArrayPtr1.c x
1  #include <stdio.h>
2
3  int main(void) {
4      // character array
5      char str[6] = "Hello";
6      // pointer ptr
7      // pointing at the character array str
8      char *ptr = str;
9
10     // print the elements of the array str
11     while (*ptr != '\0') {
12         printf("%c\n", *ptr);
13         // make the pointer ptr point at the
14         // next memory location
15         ptr++;
16     }
17     printf("End of code\n");
18     return 0;
19 }
```

```
ArrayPtr2.c x
1  #include <stdio.h>
2
3  int main(void) {
4
5      // character array
6      char str[6] = "Hello";
7      // pointer ptr
8      // pointing at the character array str
9      char *ptr = str;
10     // print the elements of the array str
11     for(int i=0; i<6; i++)
12         printf("%c\n", *(ptr+i));
13
14     printf("End of code\n");
15
16     return 0;
17 }
```

You can change  $*(ptr+i)$  with:  $*(str+i)$ ,  
 $ptr[i]$ , or  $str[i]$

# Pointers and Two Dimensional Array

		col →			
		0	1	2	3
row ↓	0	1	2	3	4
	1	5	6	7	8
	2	9	10	11	12

```
int num[3][4] = {  
    {1, 2, 3, 4},  
    {5, 6, 7, 8},  
    {9, 10, 11, 12}  
};
```

row-wise memory allocation

	<— row 0 —>				<— row 1 —>				<— row 2 —>			
value	1	2	3	4	5	6	7	8	9	10	11	12
address	1000	1002	1004	1006	1008	1010	1012	1014	1016	1018	1020	1022

↑

first element of the array num

- ▶ The compiler will **allocate the memory** for the above two dimensional array **row-wise** meaning the **first element of the second row will be placed after the last element of the first row.**

# Pointers and Two Dimensional Array

If we want to get the value at any given row, column of the array then we can use the following formula.

$$\text{arr}[i][j] = *(\text{ptr} + (i \times \text{no\_of\_cols} + j))$$

```
2_DimArrayPtr.c x
1  #include <stdio.h>
2
3  int main(void) {
4      // 2d array
5      int num[3][4] = {
6          {1, 2, 3, 4},
7          {5, 6, 7, 8},
8          {9, 10, 11, 12}
9      };
10     // pointer ptr pointing at array num
11     int *ptr = &num[0][0];
12     // other variables
13     int
14         ROWS = 3,
15         COLS = 4,
16         TOTAL_CELLS = ROWS * COLS,
17         i;
18     // print the elements of the array num via pointer ptr
19     for (i = 0; i < TOTAL_CELLS; i++)
20         printf("%d ", *(ptr + i));
21
22     printf("\n\n");
23     return 0;
24 }
```

```
2_DimArrayPtr2.c x
1  #include <stdio.h>
2  int main(void) {
3      // 2d array
4      int num[3][4] = {
5          {1, 2, 3, 4},
6          {5, 6, 7, 8},
7          {9, 10, 11, 12}
8      };
9      int
10         ROWS = 3,
11         COLS = 4,
12         i, j;
13     // pointer
14     int *ptr = &num[0][0];
15     // print the element of the array via pointer ptr
16     for (i = 0; i < ROWS; i++) {
17         for (j = 0; j < COLS; j++) {
18             printf("%3d ", *(ptr + (i * COLS + j)));
19             // printf("%3d ", (*(num + i) + j));
20         }
21         printf("\n");
22     }
23     return 0;
}
```

# Pointers and Two Dimensional Array

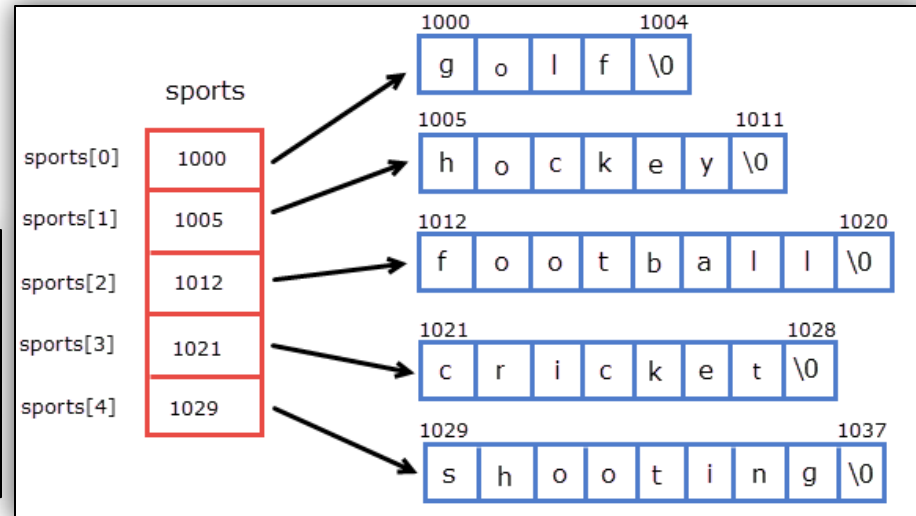

# Array of pointers

- Arrays can contain pointer.
- Can access multiple arrays with arrays of pointers.

```
char sports[5][15] = {  
    "golf",  
    "hockey",  
    "football",  
    "cricket",  
    "shooting"  
};
```

```
char *sports[5] = {  
    "golf",  
    "hockey",  
    "football",  
    "cricket",  
    "shooting"  
};  
  
//you can even remove the number of rows
```

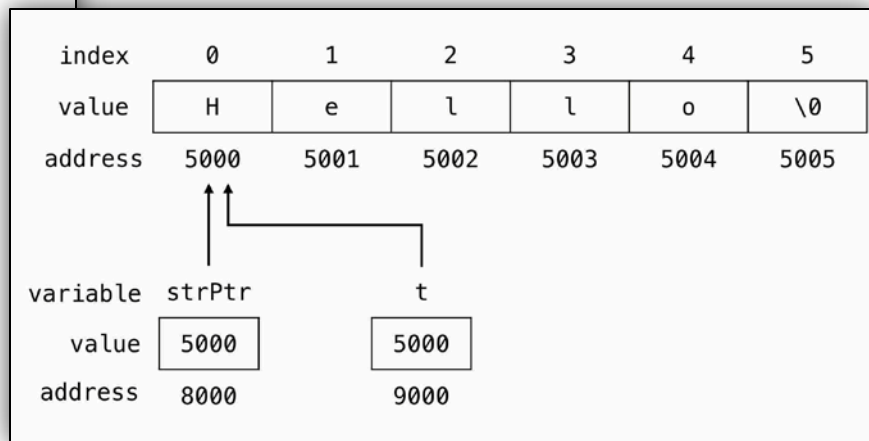

1000	g	o	l	f	\0	\0	\0	\0	\0	\0	\0	\0	\0	\0	1015
1016	h	o	c	k	e	y	\0	\0	\0	\0	\0	\0	\0	\0	1031
1032	f	o	o	t	b	a	l	\0	\0	\0	\0	\0	\0	\0	1047
1048	c	r	i	c	k	e	t	\0	\0	\0	\0	\0	\0	\0	1063
1064	s	h	o	o	t	i	n	g	\0	\0	\0	\0	\0	\0	1079

# Pointers and Strings

```
CopyArrayPtr.c x
1
2  #include <stdio.h>
3
4  int main(void) {
5
6      // pointer variable to store string
7      char *strPtr = "Hello";
8      char x[6]; // empty array
9      // temporary pointer variable
10     char *t, *t2;
11
12     printf("%s\n", strPtr);
13     t = strPtr;
14     t2 = x;
15
16     // print the string
17     while(*t != '\0') {
18         *t2 = *t; // using the pointers to copy strPtr to x
19         // move the t pointer to the next memory location
20         t++;
21         t2++;
22     }
23     printf("%s\n", x);
24     return 0;
25 }
```

# Pointers and multidimensional array

```
MultiDimArrayPtr.c X
1  #include <stdio.h>
2  int main(void) {
3      int i,j;
4      char * SpringSeason[]={ "March", "April", "May"};
5      char * SummerSeason[]={ "June", "July", "August"};
6      char * FallSeason[]={ "September", "October", "November"};
7      char * WinterSeason[]={ "December", "January", "February"};
8
9      char ** Sasons[4]; // 2D array of strings (3D)
10     Sasons[0]=SpringSeason;
11     Sasons[1]=SummerSeason;
12     Sasons[2]=FallSeason;
13     Sasons[3]=WinterSeason;
14
15     for (i = 0; i < 4; i++)
16     { for (j = 0; j < 3; j++)
17         printf("%15s", Sasons[i][j]);
18         //printf("%s \n", (*(Sasons+i)+j));
19         printf("\n");
20     }
21     return 0;
22 }
```

# Pointers and Functions – Call by Value and Call by Reference

---

- ▶ There are two ways we can pass parameters(arguments) to a function:
  - Call by value – i.e., passing a copy of the variable.
  - Call by reference – this involves pointers, passing the memory address of the variable.
- ▶ Call by value (pass by value) will not change the original variable but its copy.
- ▶ Using call by reference (pass by reference) the arguments are not passed with their values, but with their addresses. Thus, all modifications on arguments effect the original variable.

# Call by value – example

CallByValue.c x

```
1  #include <stdio.h>
2  void add10(int); // function declaration
3  int main(void) {
4      int num = 10; // integer variable
5      printf("Value of num before function call: %d\n", num); // print value of num
6
7      add10(num); // pass by value
8      printf("Value of num after function call: %d\n", num); // print value of num
9      return 0;
10 }
11 // function definition
12 void add10(int n) {
13     n = n + 10;
14     printf("Inside add10(): Value %d\n", n);
15 }
```

Output

inside the main() function

int num = 10;

variable num  
created  
value 10  
address 1000

function call

add10(num)  
passing value  
of num

back from add10()  
function

variable num  
value 10  
address 1000  
value of num  
unchanged

timeline

n gets a copy  
of num value

variable n  
value 10  
address 2000

adding  
10

n = n + 10;

variable n  
value 20  
address 2000

inside the add10() function

# Call by reference - example

CallByReference.c x

```
1  #include <stdio.h>
2  void add10(int *); // function declaration
3  int main(void) {
4      int num = 10; // integer variable
5      printf("Value of num before function call: %d\n", num); // print value of num
6
7      add10(&num); // pass by reference
8      printf("Value of num after function call: %d\n", num); // print value of num
9      return 0;
10 }
11 // function definition
12 void add10(int *n) {
13     *n = *n + 10;
14     printf("Inside add10(): Value %d\n", *n);
15 }
```

Output

inside the main() function

int num = 10;

variable num  
created

variable num  
value 10  
address 1000

function call

add10(&num)

passing address  
of num

back from add10()  
function

variable num  
value 20  
address 1000  
value of num  
changed

timeline

n points  
at num

variable n  
value 1000  
address 2000

adding  
10

\*n = \*n + 10;  
variable num  
value 20  
address 1000

inside the add10() function

# Call by Reference

---

- ▶ If your **function** has to **return more than one value**, **pass by reference usage is necessary**.
- ▶ Because **return keyword** can only **return one value** from function.
- ▶ For **example**, we want to write **a division function that gives division result and remainder**.
- ▶ **In this case**, return keyword can only return one value, **second value could be returned by reference method**.(or you can return both values by reference)

# Call by Reference – example 2

CallByReferenceDiv.c

```
1  #include<stdio.h>
2  void div(int , int , int *, int *);
3
4  main() {
5      int a = 76, b = 10;
6      int q, r;
7      div(a, b, &q, &r);
8      printf("Quotient is: %d\nRemainder is: %d\n", q, r);
9  }
10
11 void div(int a, int b, int *quotient, int *remainder) {
12     *quotient = a / b;
13     *remainder = a % b;
14 }
```

CallByReferenceDiv2.c

```
1  #include<stdio.h>
2  int div(int , int , int *);
3
4  main() {
5      int a = 76, b = 10;
6      int q, r;
7      q= div(a, b, &r);
8      printf("Quotient is: %d\nRemainder is: %d\n", q, r);
9  }
10
11 int div(int a, int b, int *remainder) {
12
13     *remainder = a % b;
14     return a / b;
15 }
```

---

Thanks 😊
